ABSTRACT

A reclassification of *Neoculex* proposed here is based on the comparative morphology of the male terminalia as well as on other correlated external characters of the adults. In this scheme, three subgenera: *Neoculex, Maillotia* and *Eumelanomyia* instead of two, *Neoculex* and *Mochthogenes*, as proposed by Edwards (1932), are recognized. The subgenera *Maillotia* and *Eumelanomyia* are resurrected from synonymy with *Neoculex* and *Mochthogenes* which Edwards (1930) treated as a full subgenus is suppressed by synonymizing it with *Eumelanomyia*. The species *tricuspis* Edwards 1930 is transferred to *Culiciomyia* and *sumatranus* Brug 1931 and *caeruleus* King & Hoogstraal 1947 to *Lophoceraomyia*.

Over 80 species previously assigned to *Neoculex* and *Moch-thogenes* in the synoptic catalog of Stone et al. (1959) and Stone (1961, 1963, 1967, and 1970) are placed in various species groups of the three subgenera. Keys to the subgenera, groups and subgroups are provided and each category is briefly defined with regard to systematics and zoogeography.

A PROPOSED RECLASSIFICATION OF *NEOCULEX* DYAR BASED PRINCIPALLY ON THE MALE TERMINALIA¹

By

Sunthorn Sirivanakarn²

INTRODUCTION AND HISTORY OF PREVIOUS CLASSIFICATIONS

The subgenus Neoculex Dyar 1905 in the broad sense of Edwards (1932, 1941) has remained perhaps one of the most poorly understood subgenera of Culex. The subgenus, as defined by Edwards, with the material at his disposal, is a heterogeneous array of several distinct lineages of 70 or more species known at the present time. These species are mostly restricted to certain zoogeographical regions. The one exception is territans (Walker, 1856) from North America which is also known to occur in some European countries. Records of species from different areas are as follows: 33 from the Ethiopian region, 8 from the Mediterranean subregion, 9 from the Oriental region, 9 from the Australasian region (Australia and New Guinea), 5 from the South Pacific and 6 from the Nearctic region.

No attempt has yet been made to revise *Neoculex* on a world basis, but there have been a good number of taxonomic papers dealing with local species in several regional works (see references below). Edwards' subgeneric interpretation and his internal classification have been largely followed by a few critical comments. Mattingly & Marks (1955) and Belkin (1962) pointed out the weaknesses regarding the relationships between Edwards' species groups, but these were limited to brief statements. A critical examination of Edwards' scheme is made here to set a stage for the further development of a phylogenetic classification. The main purpose of the present attempt is to lay out certain basic and significant features not used by Edwards in his interpretation of *Neoculex*. The basis of this discussion includes the study of his work and the re-examination of almost all species which he used in devising his scheme.

Edwards' interpretation of Neoculex was based on many superficial characters which greatly overlap with those of other subgenera, particularly Mochthogenes, Lophoceraomyia, Culiciomyia and to some extent even with those of other Culex subgenera. He apparently defined all species involved on the basis of the simple phallosome of the male terminalia which he did not describe in detail. This has resulted in some incorrect subgeneric assignments of certain species to the subgenus. Edwards' description of the male phallosome is brief and also appears to conceal a number of significant features with regard to its varied shape and the relative position of the tergal bridge which connects the two lateral plates. This point will be considered and illustrated below in my interpretation of various species groups. It suffices to mention that the shape of the phallosome is quite constant in certain lineages and appears to be strongly differentiated. The other characters which appear to be more or less consistently correlated with the differences in shape of the phallosome, but were not considered by Edwards are: texture of the spicules of the

² Southeast Asia Mosquito Project, Department of Entomology, Smithsonian Institution, Washington, D. C. 20560.

proctiger crown, number of rodlike setae in the proximal division of the subapical lobe and the presence or absence of scale patches on the pleura. A brief

summary of Edwards' scheme is as follows:

In grouping species in the subgenus Neoculex, Edwards (1932) suppressed 3 genera of Theobald (1907, 1910) including Maillotia, Eumelanomyia and Protomelanoconion by reducing them to synonymy with the genus Neoculex Dyar (1905). The genus Neoculex, as originally conceived by Dyar, was based on C. territans (Walker 1856) from North America, a form which shows a great deal of superficial resemblance to some members of the pipiens group of subgenus Culex. In clarifying his classification, Edwards separated 3 groups in the subgenus, namely: group A. Neoculex s. str. or apicalis group, group B. Eumelanomyia or albiventris group and group C. Protomelanoconion or uniformis group. These groups are distinguished by the relative length of male palpi, texture of decumbent scales on vertex and presence or absence of apical bands on abdominal terga. Later, in his work on the Ethiopian species, he (1941) split group A. into 3 groups by incorporating features of the female buccopharyngeal armature, color pattern of pleural integument and certain conspicuous ornamentation. This subdivision resulted in: group A. pulchrithorax, group B. Neoculex s. str. and group C. rima group. The original groups B. and C. became groups D. and E. The first and second treatments are essentially similar in outline and scope and in 1947, King & Hoogstraal followed this scheme by recognizing another additional group F. pedicellus from New Guinea. A critical study of Edwards' system indicates that he lumped a number of unrelated forms in *Neoculex s. str.* group and his group characters largely overlapped and remained confused. The relationships between these groups are not at all clear and the entire treatment appears to suffer from the lack of uniformity in most parts. A broader examination of his system reveals the difficulties he experienced in ranking certain species groups. This is quite obvious from his treatment of Mochthogenes as a subgenus separated from the Protomelanoconion or uniformis group of Neoculex based on the relative length of the male palpi which are as short as in the female of all Mochthogenes species but are longer in the Protomelanoconion species. Although such treatment is convenient in practice since species of Mochthogenes share these characters, the relationship with Protomelanoconion on the basis of the male terminalia and many other characters do not seem to warrant its separation. The two groups, as recently pointed out by Bram (1969), are also so similar in the larval stage to be treated in the same subgenus.

In my current study of *Neoculex* in Southeast Asia and other adjacent areas, the difficulty presented by Edwards' classification are illustrated by the following examples. Four species, namely *tenuipalpis* Barraud 1924, *hayashii* Yamada 1917, *hackeri* Edwards 1923 and *kiriensis* Klein & Sirivanakarn 1969, all with extremely similar male terminalia and several external characters, but with palpi of different lengths, will, according to Edwards, have to be placed in either *Neoculex* or *Mochthogenes*. Similarly *tricuspis* Edwards 1930, at present in *Neoculex*, should in fact be reassigned to *Culiciomyia*; sumatranus Brug 1931 and caeruleus King & Hoogstraal 1947 on the other hand

rightly belong to Lophoceraomyia.

In developing the following scheme of reclassification, I have been fortunate in having the opportunity to re-examine several authenticated specimens, including the types and identified specimens of species used by Edwards in his revision of the world fauna, by Mattingly (1953) in his work on the Mediterranean species and other type specimens from several areas, at the British Museum. In addition, while undertaking the revision of the Indomalayan species at Southeast Asia Mosquito Project, I have also seen specimens of the North American species and others from several areas in the reference collections of the United States National Museum.

The history of the classification of *Neoculex* and *Mochthogenes* is summarized in table I below.

4. mochthogenes group (subgroups: hinglungensis, uncinatus, inconspicuosus, malayi, castrensis, femineus, otachati, tenuipalpis)

A CONSIDERATION OF THE PROPOSED RECLASSIFICATION

The adults of all species, previously assigned to *Neoculex* and *Mochthogenes* and to be considered at present are generally distinguished from other *Culex* subgenera as follows: From *Lophoceraomyia* by the absence of scale tufts on the male antennal flagellum; from *Culiciomyia* by the absence of a row of lanceolate scales on the ventral surface of segment 3 of the male palpus; from *Acalleomyia* by the narrow scutellar scales; from *Barraudius* and *Lasiosiphon* by having tarsomere 1 of the hind tarsus about as long as the tibia and by the absence of scales on the basimere of the male terminalia; from *Culex* and *Lutzia* by the absence of basal sternal processes on the proctiger of the male terminalia; and from all New World subgenera including *Melanoconion*, *Aedinus*, *Isostomyia*, *Carrollia*, *Mochlostyrax*, *Microculex*, and *Micraedes* by the absence of a basal hook on the lateral plate of the male phallosome.

Taxonomic Characters. As indicated earlier in the introduction, basis to the present interpretation of various species groups and their reclassification is the comparative morphology of the phallosome and other correlated characters in the proctiger crown and subapical lobe of the male terminalia. The shape of the phallosome is not only of taxonomic significance in this interpretation, but also provides, in addition to other conspicuous characters, a clear-cut separation of all species involved from other closely related subgenera of Culex. It appears that there are at least 3 basic types of male phallosome present among species of Neoculex as interpreted by Edwards. These are: Type I tubular, elongate with the axis of the two lateral plates more or less parallel and with the tergal bridge located above the middle or near the apex of the lateral plate; Type II more or less globular or subspherical with tergal bridge as in I or at the middle of the lateral plate; Type III slightly modified from type II in being oval with tergal bridge at or slightly below the midpoint of the lateral plate. In the proctiger crown, there are two kinds of spicules; one of these is flat and blunt, the other fine and pointed. In certain spicules; one of these is flat and blunt, the other fine and pointed. lineages, the crown may consist of flat or fine spicules only, or a mixture of both. In the subapical lobe, there is a great deal of variation in the development of parts and the number of specialized setae, however, the features which appear to be correlated with different types of phallosome are the presence of 2 or 3 rodlike setae in the proximal division and the presence or absence of a leaflet (foliform seta) in the distal division.

In the external morphology, a number of conspicuous characters which are of practical value in separating species groups at various levels are: (1) presence or absence of pleural scaling, (2) color and texture of scutal scales, (3) relative length of male palpus and (4) presence or absence of pale abdominal banding. These and a few other features may be correlated with the terminalia to a certain extent and have been considered here in developing key and group characters.

The female buccopharyngeal armature and the immature stages may also prove to be useful in developing this classification but because of insufficient material, no attempt has been made here to incorporate them with the present scheme.

Systematics. In the present interpretation, I believe it would be much sounder, considering both the comparative male terminalia and, to some extent, zoogeography to recognize at least 3 principal subgeneric categories among 80 or more species known at the present time. In the general outline presented below, I recognize Neoculex, Maillotia and Eumelanomyia as distinct subgenera based on differences in the shape of the male phallosome as discussed above. The subgenera Maillotia and Eumelanomyia are resurrected from synonymy under Neoculex and the subgenus Mochthogenes is downgraded to a species group of Eumelanomyia.

These three subgenera are further subdivided into groups and subgroups wherever it is appropriate to accommodate all species presently listed in

Neoculex and Mochthogenes in Stone et al. (1959) and Stone (1961, 1963, 1967 and 1970), except caeruleus King & Hoogstraal 1947; sumatranus Brug 1931 and tricuspis Edwards 1930. The first two of these I am transferring to Lophoceraomyia and tricuspis to Culiciomyia. The assignment of some species to groups below the subgeneric level has been based only on the published descriptions and may need future realignment in order to indicate a more accurate affinity.

OUTLINE OF THE PROPOSED SCHEME OF RECLASSIFICATION

Subgenus I. NEOCULEX Dyar 1905.

- (1). territans group with territans (Walker 1856); apicalis Adam 1903; boharti Brookman & Reeves 1950; reevesi Wirth 1948; arizonensis Bohart 1950; derivator Dyar & Knab 1906; deserticola Kirkpatrick 1924; judaicus Edwards 1926; impudicus Ficalbi 1889; rubensis Sasa & Takahashi 1948 and martinii Medschid 1930.
- (2). pseudomelanoconia group with pseudomelanoconia (Theobald 1907); postspiraculosus Lee 1944; chaetoventralis (Theobald 1910); douglasi Dobrotworsky 1956; latus Dobrotworsky 1956; fergusoni (Taylor 1914); cheesmanae Mattingly & Marks 1955; dumbletoni Belkin 1962; gaufini Belkin 1962 and millironi Belkin 1962.
- (3). crassistylus group with crassistylus Brug 1934; pedicellus King & Hoogstraal 1947 and leonardi Belkin 1962.

Subgenus II. MAILLOTIA (Theobald 1907).

- (1). pulchrithorax group with pulchrithorax Edwards 1914.
- (2). hortensis group with hortensis Ficalbi 1889; arbieeni Salem 1938 and quettensis Mattingly 1955.
- (3). seyrigi group with seyrigi Edwards 1941; peringueyi Edwards 1924; salisburensis Theobald 1901 and avianus de Meillon 1943.

Subgenus III. EUMELANOMYIA (Theobald 1909).

- (1). eumelanomyia group with albiventris Edwards 1922; andersianus Edwards 1941; acrostichalis Edwards 1941; vinckei Hamon, Holstein & Rivola 1961(1962); kanyamwerima Someren 1951; kilara Someren 1951; garioui Bailly-Choumara & Rickenbach 1966.
- (2). rubinotus-rima group
 - (a). rubinotus subgroup with rubinotus Theobald 1901; kingianus Edwards 1927; andreanus Edwards 1927; pseudoandreanus Bailly-Choumara 1965 and simplicicornis Edwards 1930.
 - (b). rima subgroup with rima Theobald 1901; subrima Edwards 1941; galliardi Edwards 1941; calabarensis Edwards 1941; wigglesworthi Edwards 1941; insignis (Carter 1911); sunyaniensis Edwards 1941; albertianus Edwards 1941; wansoni Worlfs 1945; adami Hamon & Mouchet 1955; laplantei Hamon, Adam & Mouchet 1955;

amaniensis Someren & Hamon 1964 and chauveti Brunhes & Rambelo 1968.

- (3). protomelanoconion group with brevipalpis (Giles 1902); stellatus Someren 1947 and horridus Edwards 1922.
- (4). mochthogenes group
 - (a). hinglungensis subgroup with hinglungensis Chu 1957; culionicus Delfinado 1966; tricontus Delfinado 1966 and cataractarum Edwards 1923.
 - (b). uncinatus subgroup with uncinatus Delfinado 1966.
 - (c). inconspicuosus subgroup with inconspicuosus (Theobald 1908); simpliciforceps Edwards 1935; castor de Meillon & Lavoipierre 1944; hamoni Brunhes et al. 1967; mijanae Brunhes et al. 1967 and orstom Brunhes et al. 1967; perhaps also bokorensis Klein & Sirivanakarn 1969.
 - (d). malayi subgroup with malayi (Leicester 1908); laureli Baisas 1935 and yeageri Baisas 1935.
 - (e). castrensis subgroup with castrensis Edwards 1922; foliatus Brug 1932; latifoliatus Delfinado 1966; chiyutoi Baisas 1935 and shrivastavii Wattal, Kalra & Krishnan 1966.
 - (f). femineus subgroup with femineus Edwards 1926.
 - (g). otachati subgroup with otachati Klein & Sirivanakarn 1969.
 - (h). tenuipalpis subgroup with tenuipalpis Barraud 1924; hayashii Yamada 1917; hackeri Edwards 1923; pluvialis Barraud 1924; kiriensis Klein & Sirivanakarn 1969; selai Klein & Sirivanakarn 1969; campilunati Carter & Wijesundara 1948; and perhaps also okinawae Bohart 1953; lini Lien 1968; khazani Edwards 1922; and iphis Barraud 1924.

KEY TO THE SUBGENERA

2(1). Proctiger with crown of flat and blunt spicules entirely or with some coarse pointed spines in addition; pleural scaling present; scutal scales usually pale or sand-colored..... Subgenus MAILLOTIA Proctiger usually with a crown of fine pointed spines only, or sometimes with a few coarse ones in addition; pleural scaling entirely absent; scutal scales predominantly dark brown..... Subgenus EUMELANOMYIA

Subgenus I. NEOCULEX Dyar

1905 Neoculex Dyar, Proc. ent. Soc. Wash. 7:45; Type species Culex territans Walker 1856, original designation.

1932 Culex (Neoculex) in part of Edwards, Gen. Insect. Dipt. Fam. Culicidae, Fasc. 194:193-195.

Culex (Neoculex) in part of Edwards (1941: 249-270); King & Hoogstraal

Culex (Neoculex) in part of Edwards (1941: 249-270); King & Hoogstraal (1947: 65-69); Mattingly & Marks (1955: 166-175); Dobrotworsky (1956: 105-114); Belkin (1963: 238-247); and Dobrotworsky (1965: 193-202).

Subgeneric Characters. As diagnosed in the key to subgenera, with the following additional features. Medium to large sized species, wing length over 3.0 mm. Head. Male palpi as long as or longer than proboscis; antenna strongly plumose. Thorax. Scutal scales usually predominantly pale, sometimes with striking pattern of coloration or entirely dark; pleuron usually with extensive broad scale patches on propleuron, upper corner and posterior lower border of sternopleuron and anterior upper mesepimeron, sometimes also on postspiracular area and prealar area; rarely absent entirely. Abdomen. Terga with or without apical or basal bands, sometimes with apicolateral pale spots. Male Terminalia. (Fig. 1) Phallosome elongate, tubelike, H-shaped in tergal view or slightly modified, tergal bridge usually near to or almost at the apex of lateral plate, rarely at the middle, a few denticles present or absent; proctiger with crown of flat and blunt spicules only or also with a few coarse pointed spines in addition; subapical lobe always with 2 long rodlike setae in the proximal division; distal division with only narrow flattened setae, broad leaflets absent.

Systematics. Species which are strictly or provisionally placed within this subgenus are generally similar in the configuration of the phallosome, proctiger and features of the subapical lobe as described above. They may be well divided into 3 groups on the basis of slight differences in phallosome structure, presence or absence of pleural scaling as in the following key.

KEY TO THE GROUPS OF SUBGENUS NEOCULEX

1. Phallosome uniformly tubular in shape with tergal bridge between the midpoint and apex of lateral plates; pleural scaling always present; abdominal terga with apical pale bands; scutal scales sand-colored.... territans group Phallosome broad in apical half, narrow in basal half; tergal bridge nearly at or below the apex of lateral plates; pleural scaling present or absent; abdominal terga with apical or basal pale bands, apicolateral spots or sometimes entirely dark; scutal scales usually entirely dark or sometimes 2 bseudomelanoconia group

sternopleuron crassistylus group

TERRITANS GROUP

This group includes 6 species from the Nearctic (mainly North America); territans (also known in Europe), apicalis, boharti, reevesi, arizonensis and derivator; 1 species from northern Palearctic of the Oriental region: rubensis and 4 species from the Mediterranean, namely deserticola, judaicus, impudicus and martinii. The group can be easily recognized by the predominantly pale or sand-colored scutal scales, presence of broad scale patches on 3 or 4 areas of pleura and presence of apical banding on abdominal terga, as indicated in the key.

PSEUDOMELANOCONIA GROUP

This group contains 6 species from Australia: pseudomelanoconia, chaetoventralis, douglasi, fergusoni, latus and postspiraculosus and 4 species from the South Pacific: cheesmanae, dumbletoni, gaufini and millironi. The extent of the pleural scaling is variable, but the shape of the phallosome and the characteristic crown of the proctiger are very constant in nearly all species involved. According to Dobrotworsky (1956: 105) the members of this group could be well divided into two subgroups, one involving fergusoni and latus with apical abdominal banding or apicolateral abdominal spots and presence of pleural scaling, the other involving douglasi and pseudomelanoconia with basal abdominal banding and reduced pleural scaling.

CRASSISTYLUS GROUP

Two members of this group: crassistylus and pedicellus are known from New Guinea and the other one, leonardi, is from the South Pacific. They are strikingly differentiated from the other two groups in the almost complete absence of pleural scaling, modified shape of distimere, development of parts of the subapical lobe and in having striations on the upper tergal surface of the lateral plate of the phallosome. They are probably derived from members in the pseudomelanoconia group.

Subgenus II. MAILLOTIA (Theobald)

1907 Maillotia Theobald, Mon. Cul. 4:274; Haplotype: pilifera (presently known as hortensis).

Culex (Neoculex) in part of Edwards (1932: 193); Edwards (1941: 249);

Mattingly (1955: 376-389).

Subgeneric Characters. As given in the key to the subgenera with the following additional description. Very similar in general external features to the territans group of subgenus Neoculex, but pleural scaling is more extensive, sometimes scale patch also present on prosternum and scutal scales rather coarse. Male Terminalia. (Fig. 2) Phallosome short, broad, oval, subspherical or cup-shaped from tergal view, tergal bridge at or just above the midpoint of lateral plates, denticles not developed or sometimes only a few ones present on apex; proctiger heavily sclerotized with a relatively large crown of flat and blunt spicules arranged in comblike fashion or sometimes mixed with coarse pointed spines in the form of a tuft; proximal division of subapical lobe with 2 or sometimes 3 rodlike setae, distal division with few short narrow setae or none: distimere more or less modified.

short narrow setae or none; distimere more or less modified.

Systematics. This is perhaps the most primitive of the three subgenera. It is rather heterogeneous consisting of species which are perhaps better placed with either Neoculex or Eumelanomyia. However, as they show the type of phallosome, and other features, somewhat intermediate between the other two subgenera, I think it is probably better to consider them as belonging to a subgenus of their own. As they are either exclusively Ethiopian or Mediterranean, it seems better to treat them this way.

KEY TO THE GROUPS OF SUBGENUS MAILLOTIA

Head, scutum and pleuron with a pattern of silvery white scale lines contrasting sharply with dark scaled background; apex of proctiger of male terminalia with a heavily sclerotized plate bearing a small crown of pulchrithorax group Head, scutum and pleuron without above ornamentation; apex of proctiger of male terminalia without heavily sclerotized plate, but with crown of flat and blunt spicules or of coarse pointed spines 2 2(1). Proximal part of subapical lobe with 2 rodlike setae; lateral plate of phallosome without denticles hortensis group Proximal part of subapical lobe with 3 rodlike setae; apex of lateral plate of

PULCHRITHORAX GROUP

phallosome with some denticles seyrigi group

This group, as keyed above, corresponds to Edwards' group A (1941: 249) with only one species, namely, the Ethiopian *C. pulchrithorax*. Its outstanding ornamentation on the dorsum of head, scutum, pronotum and upper pleura is very distinctive as described and illustrated by Edwards (1941: 254). The female buccopharyngeal armature is, however, rather similar to species in the *seyrigi* group.

HORTENSIS GROUP

This group contains 3 or perhaps more species from the Mediterranean. Their external characters are more or less similar to the territans group of Neoculex, but with propleural scale patch extended to prosternum in some species. At present, 3 forms, namely hortensis, arbieni and quettensis are grouped together here. They appear to show the characters of the subgenus better than the other two groups.

SEYRIGI GROUP

I tentatively place 4 forms, namely seyrigi, peringueyi, salisburensis and avianus, all from the Ethiopian region, in this group, based on the characters given in the key. They are similar to members of the hortensis group in external features, but the male phallosome and other features of the male terminalia resemble members in the subgenus Eumelanomyia.

Subgenus III. EUMELANOMYIA Theobald

1909 Eumelanomvia Theobald, Mon. Cul. 5:240; Haplotype: inconspicuosus

(presently known as albiventris).
1910 Protomelanoconion Theobald, Mon. Cul. 5:462; Haplotype: fusca (presently known as horridus).

1930 Culex (Mochthogenes) Edwards, Bull. ent. Res. 21:306; Type: C. malaya Leicester 1908. Culex (Neoculex) in part of Edwards (1932: 193-195); Edwards (1951: 249-269); Barraud (1934:347-352); Bohart & Ingram (1946); Bohart (1953:187); Delfinado (1966: 124-128); Bram (1967: 23-32).

Culex (Mochthogenes) of Edwards (1932:195; 1941:277-279); Barraud (1934:352-359); Baisas (1935:175-177); Delfinado (1966:128-135); Bram (1967:33-42).

Subgeneric Characters. As indicated in the key to subgenera, with the following additional description. Small to medium sized, wing length usually not more than 3.0 mm., dark brown to black species. Head. Male palpus from 0.2 to longer than the length of proboscis; antennal flagellomeres 1-10 usually with a single whorl of long hairs each, sometimes also with a much smaller whorl of short but conspicuous hairs in addition (Fig. 3). Thorax. Scutal scales narrow and usually entirely dark, rarely pale; pleural scaling absent or only a few scales present on upper corner of sternopleuron. Abdomen. Terga entirely dark or with apical bands, apicolateral pale spots, rarely with basal bands. Male Terminalia. (Fig. 3) Phallosome small, generally broad, oval or subspherical in shape; tergal bridge at or below the midpoint of lateral plates; usually with several denticles over the upper tergal surface, rarely bare; proctiger with small dark crown of fine spinelike spicules, some coarse ones present or absent; proximal division of subapical lobe always with 3 rodlike setae; distal division usually with at least a broad leaflet; distimere slender, sickle-shaped or else modified.

Systematics. Members of this subgenus can be easily distinguished from the other two subgenera by smaller size, dark scaled scutum and the absence of scale patches on the pleura. The phallosome is variable among different species but all are remarkably constant with regard to shape and position of tergal bridge and do not appear to overlap in these characters with species in *Neoculex*. The fine texture of the spicules of the proctiger crown and the presence of 3 rodlike setae in the proximal division of the subapical lobe

are also characteristics of this subgenus.

This subgenus contains the majority of species from the Ethiopian region and the Indomalayan part of the Oriental region. The number of species involved is the largest of the 3 subgenera recognized here. They are divided into 4 major groups as follows:

KEY TO THE GROUPS OF SUBGENUS EUMELANOMYIA

1.	Male palpus as long as or longer than proboscis; flagellomeres 1 to 10 of male antenna each with a single large whorl of long hairs	
2(1).	Decumbent scales in center of vertex broad; acrostichal bristles absent; tergal bridge of phallosome present or absent	;
3(1).	Male palpus about 0.75 the length of pro- boscis; acrostichal bristles absent; lower anterior mesepimeral bristle absent Male palpus usually about 0.2 the length of proboscis, sometimes longer to about 0.75; acrostichal bristles present; lower anterior mesepimeral bristle usually	
	present	mochthogenes group

EUMELANOMYIA GROUP

This group corresponds to Edwards' group B (1932) and group D. (1941) or albiventris group. Five species, all from the Ethiopian region are placed here: albiventris, andersianus, vinckei, acrostichalis and kanyamwerima and perhaps also kilara and garioui. The group is characterized as in the key and may be further subdivided into two subgroups on the basis of presence or absence of a tergal bridge of the phallosome. Certain members of this group appear to show affinity to the subgenus Culiciomyia.

RUBINOTUS-RIMA GROUP

This group corresponds to the *rima* group or group C and *Neoculex s. str.* group, in part, of Edwards (1941). It could be subdivided into 2 subgroups: 1) *rubinotus* subgroup with *rubinotus*, *kingianus*, *andreanus*, *pseudo-andreanus* from the Ethiopian region and *simplicicornis* from the Indomalayan

³ As illustrated, the term "normal whorl" as used here refers to the large tuft of 10 to over 20 long hairs arising from a series of tubercles encircling the middle part of each flagellomere, whereas the term "small or minor whorl" refers to a much smaller tuft with 4-8 short hairs arising near the junction of the flagellar segments.

area (Borneo) by having abdominal terga entirely dark and by having the pleural integument uniformly dark brown; and 2) rima subgroup with rima, subrima, galliardi, calabarensis, wigglesworthi, insignis, albertianus, wansoni and perhaps also sunyaniensis and others as listed by having apical band or apicolateral spots on abdominal terga and by having a pattern of dark and pale areas on the pleura. The members in the rubinotus subgroup show strong affinity to the subgenus Lophoceraomyia on the basis of several characters indicating that the latter subgenus is probably derived from them.

PROTOMELANOCONION GROUP

This group includes *brevipalpis*, a dominant form from several areas in the Oriental region, horridus from the Ethiopian region and *stellatus* from Seychelles. It is closely related to the *mochthogenes* group, but with longer male palpi and differing in other constant features as indicated in the key.

MOCHTHOGENES GROUP

This group is dominant in the Indomalayan areas and other southern parts of the Oriental region in which it is represented by many distinct lineages (see list above). It is perhaps represented by a single lineage (inconspicuosus subgroup) in the Ethiopian region. In the South Pacific, it is represented by a single species (femineus). I recognize 8 subgroups in this group. They are separated as follows:

KEY TO THE SUBGROUPS OF GROUP MOCHTHOGENES

1.	Decumbent scales in the center of vertex entirely or predominantly broad along anterior ocular line
2(1).	Distimere of male terminalia simple, sickle shaped
3(2).	Lateral plate of phallosome without large internal process; minor flagellar whorls of short hairs of male antenna present hinglungensis subgroup Lateral plate of phallosome with a large internal process; minor flagellar whorls of short hairs of male antenna absent uncinatus subgroup
4(2).	Distimere sharply angled at the middle of dorsal curvature, its basal half thick, distal half narrow and tapered to a curved spine

5(1).	Male antennal flagellar whorls with rather weak and relatively few hairs; size minute or very small, wing length usually not
	exceeding 3.0 mm
	wing length usually 3.0 mm. or more
6(5).	Abdominal terga entirely dark; phallosome of male terminalia short and oval in shape; basimere small, slender and conical in
	shape
	oval in shape femineus subgroup
7(5)	Male phallosome heavily sclerotized and dark, lateral plate rodlike and pointed with some heavy lateral teeth otachati subgroup Male phallosome weakly sclerotized and
	pale yellow or brown, lateral plate oval or subspherical in shape; teeth confined to inner tergal surface

As indicated in the above key, the *mochthogenes* group is rather complex as it contains several lineages, most of which can be easily recognized by the short male palpus more or less similar to the female. Only the *tenui-palpis* subgroup, as far as known, consists of some members with male palpi longer than those of the females. These are *tenuipalpis*, *hayashii* and *okinawae* which Edwards (1932:194-195) and Bohart (1953:187) placed with the *proto-melanoconion* group of *Neoculex s. lat.* The *femineus* subgroup is also rather anomalous in male terminalia but since it shows several characters common to most *mochthogenes* members, I place it here for the present.

Culex gamma Seguy (1924, Encycl. ent., :47) was described from larva only and cannot definitely be placed with any subgenus according to the present scheme.

ACKNOWLEDGEMENTS

I wish to thank Dr. Botha de Meillon, Project Leader, Southeast Asia Mosquito Project, Smithsonian Institution and Dr. Alan Stone, Agriculture Research Service, U.S. Department of Agriculture for their many helpful suggestions in improving the manuscript. I also wish to thank Dr. Stone for the loan of specimens from the United States National Museum and several papers on Neoculex in his private file for study and consultation. I am indebted to Dr. P. F. Mattingly for his courtesy extended to me while studying the specimens at the British Museum. Dr. John N. Belkin, Department of Zoology, University of California, Los Angeles, kindly read the manuscript and I wish to thank him for his comments and advice. I thank Mr. Vichai Malikul for his assistance with the illustrations.
